

# I-PHONE CLOSET SCANNER

---

Nirdesh Adusumilli

# REMOVING/HIDING THE EXISTING CONTENTS

---

- RoomPlan(Apple framework) models/classifies everything during the scan
- Puts the architecture of the closet(walls, floors, doors, windows, openings) in one category and other contents in the closet into another category
- Can see a 3D model of the room with/without the contents in the closet via a toggle button

# TECHNICAL ARCHITECTURE

---

- RoomPlan
  - Fast, but only accurate to centimeters
- ARKit ruler
  - Accurate after filtering + calibration
  - Raw LiDAR accuracy is  $\pm 5-10\text{mm}$
  - Raycasts the LiDAR mesh from a fixed screen-center pixel
  - Applies a calibration factor from a known 12 inch reference (ruler) to cancel systematic bias

# DEVELOPMENT PROCESS

---

- Mapped the 5 spec requirements to components before writing any code (table in README)
- Chose the architecture myself: RoomPlan for reconstruction, custom ARKit ruler for precision – RoomPlan alone can't hit 1/16"
- Used Claude Code to accelerate the Swift implementation via spec-driven prompts: the prompts specified the accuracy strategy (median-of-30 sampling, outlier rejection, calibration)
- Iterated on-device: test → find issues → refine prompt → re-test

| Requirement                             | Where it lives          | Approach                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan the closet with cameras + sensors  | Scan tab                | Apple RoomPlan drives the camera + LiDAR to reconstruct room architecture in real time.                                                                                                                                                                                                                       |
| Digitally remove/hide existing contents | Scan tab → result       | RoomPlan separates <i>architecture</i> (walls, floor, doors, windows, openings) from <i>objects</i> (clutter). The reconstruction renders both, with a <b>show/hide-contents toggle</b> to make the clutter vanish live, and an <b>architecture-only USDZ export</b> so the exported file is genuinely empty. |
| Calculate & display dimensions          | Scan tab → result       | Mode-adaptive: reach-in gets $W \times D \times H$ (1/16" + decimal inches), area, and volume; walk-in gets a 2D floor plan, footprint area, per-wall segment lengths, ceiling min-max, and labeled doors/openings — all with the scale calibration applied.                                                  |
| 1/16" accuracy + validation             | Ruler + Validation tabs | LiDAR raycast measurement with outlier-rejected median filtering, live stability readout, and a <b>known-length scale calibration</b> ; an on-device harness logs measured-vs-tape-measure error and reports % within 1/16". Full protocol in <a href="#">VALIDATION.md</a> .                                 |
| Live demo from iPhone                   | whole app               | Native app; runs live on-device. Demo script below.                                                                                                                                                                                                                                                           |

# ACCURACY, LIMITATION, VALIDATION

---

- Before Calibration: 95% of samples were within 1/16<sup>th</sup> tolerance → After Calibration: 100% of samples were within 1/16<sup>th</sup> tolerance
- Limitations: RoomPlan error ( $\pm 5$  cm per meter(3.28084 ft)), sample size
- Systematic Scale Error Before:  $\frac{|-0.013|}{12} \times 100 = 0.108\bar{3}\%$
- Systematic Scale Error After:  $\frac{|-0.002|}{12} \times 100 = 0.0167\%$
- Before calibration, the 0.1083% bias would be ~3.4 mm on a 10 ft wall
- After calibration, the 0.0167% bias would be ~0.5mm on a 10 ft wall
